## Triangular Numbers

## What are triangular numbers?

1st

2nd

3rd

4th

## Triangular Numbers

The $n$-th triangular number, $\Delta_{n}$ is $\frac{n(n+1)}{2}$

## Classic proof:

$$
\begin{aligned}
\Delta_{n} & =1+2+\cdots+n \\
\Delta_{n} & =n+(n-1)+\cdots+1 \\
2 \Delta_{n} & =(n+1)+(n+1)+\cdots+(n+1) \\
2 \Delta_{n} & =n(n+1) \\
\Delta_{n} & =\frac{n(n+1)}{2}
\end{aligned}
$$

Combinatorial Proof:

$$
\sum_{i=1}^{n} i=\sum_{i=1}^{n} \sum_{j=0}^{i-1} 1=\binom{n+1}{2}
$$

## Probabilistic Proof

Let $X$ be the sum of two uniformly-distributed $n$-sided dice.

$$
\mathbb{P}[X=k]= \begin{cases}\frac{(k-1)}{n^{2}}, & 2 \leq k \leq n+1 \\ \frac{n-i+1}{n^{2}}, & k=n+i \text { with } 2 \leq i \leq n\end{cases}
$$

Since $2 \leq X \leq 2 n$, then

$$
\begin{aligned}
1 & =\sum_{k=2}^{2 n} \mathbb{P}[X=k]=\sum_{k=2}^{n+1} \frac{k-1}{n^{2}}+\sum_{i=2}^{n} \frac{n-i+1}{n^{2}} \\
1 & =\left(\frac{1}{n^{2}}+\frac{2}{n^{2}}+\cdots+\frac{n}{n^{2}}\right)+\left(\frac{n-1}{n^{2}}+\frac{n-2}{n^{2}}+\cdots+\frac{1}{n^{2}}\right) \\
n^{2} & =(1+2+\cdots+n)+(1+2+\cdots+(n-1)) \\
n^{2} & =2(1+2+\cdots+n)-n .
\end{aligned}
$$

## Playing with Triangular Numbers

$$
1+3+6=10
$$

McMullen, inspired by this, asked himself:

- For which $k$ can we find $k$ consecutive triangular numbers that add up to be a triangular number?
- Can we find the solutions?

McMullen showed there are infinitely many solutions for $k=2,3,5$, but no solutions for $k=4$.

## Example

## $k=4$ case

Elementary manipulations show that the sum of the $k$-consecutive triangular numbers starting at $\Delta_{n}$ is $\Delta_{m}$ whenever

$$
(2 m+1)^{2}-k(2 n+k)^{2}=\frac{(k-1)\left(k^{2}+k-3\right)}{3}
$$

When $k=4$ we get

$$
(2 m+1-4 n-8)(2 m+1+4 n+8)=17
$$

From which

$$
(m, n)=(4,0),(4,-4),(-5,0), \text { and }(-5,-4)
$$

## Square $k$

> Theorem
> Let $k>4$ be a square. Then there exist $k$ consecutive triangular numbers that add up to make a bigger triangular number.

## Useful Factorization

Let $k=a^{2}$.
Then

$$
(2 m+1)^{2}-a^{2}\left(2 n+a^{2}\right)^{2}=\frac{a^{6}-4 a^{2}+3}{3}
$$

$\left(2 m+1+2 n a+a^{3}\right)\left(2 m+1+2 n a+a^{3}\right)=\frac{(a+1)(a-1)\left(a^{4}+a^{2}-3\right)}{3}$

## $k$ an even square

$$
\left(2 m+1-2 n a-a^{3}\right)\left(2 m+1+2 n a+a^{3}\right)=\frac{a^{6}-4 a^{2}+3}{3}
$$

Solving

$$
\begin{aligned}
& 2 m+1-2 n a-a^{3}=1 \\
& 2 m+1+2 n a+a^{3}=\frac{a^{6}-4 a^{2}+3}{3}
\end{aligned}
$$

yields

$$
\begin{aligned}
m & =\frac{\left(a^{4}-4\right)\left(a^{2}\right)}{12} \\
n & =\frac{a\left(a^{4}-6 a-4\right)}{12}
\end{aligned}
$$

## $k$ an odd square

## We'll consider three cases:

$$
\begin{array}{ll}
a \equiv 0 & (\bmod 3) \\
a \equiv 1 & (\bmod 3) \\
a \equiv 2 & (\bmod 3)
\end{array}
$$

## $a \equiv 1 \bmod 3$ or $a \equiv 0 \bmod 3$

$\left(2 m+1+2 n a+a^{3}\right)\left(2 m+1+2 n a+a^{3}\right)=\frac{(a+1)(a-1)\left(a^{4}+a^{2}-3\right)}{3}$
Solving

$$
\begin{aligned}
& 2 m+1-2 n a-a^{3}=a+1 \\
& 2 m+1+2 n a+a^{3}=\frac{(a-1)\left(a^{4}+a^{2}-3\right)}{3}
\end{aligned}
$$

yields

$$
\begin{aligned}
& m=\frac{a^{2}(a-1)\left(a^{2}+1\right)}{12} \\
& n=\frac{(a+2)(a-3)\left(a^{2}+1\right)}{12}
\end{aligned}
$$

## $a \equiv 2 \bmod 3$ or $a \equiv 0 \bmod 3$

$\left(2 m+1+2 n a+a^{3}\right)\left(2 m+1+2 n a+a^{3}\right)=\frac{(a+1)(a-1)\left(a^{4}+a^{2}-3\right)}{3}$
Solving

$$
\begin{aligned}
& 2 m+1-2 n a-a^{3}=a-1 \\
& 2 m+1+2 n a+a^{3}=\frac{(a+1)\left(a^{4}+a^{2}-3\right)}{3}
\end{aligned}
$$

yields

$$
\begin{aligned}
& m=\frac{a^{5}+a^{4}+a^{3}+a^{2}-12}{12} \\
& n=\frac{(a+3)(a-2)\left(a^{2}+1\right)}{12}
\end{aligned}
$$

## $k=6$

Recall

$$
(2 m+1)^{2}-k(2 n+k)^{2}=\frac{(k-1)\left(k^{2}+k-3\right)}{3}
$$

When $k=6$ :

$$
x^{2}-6 y^{2}=65
$$

Therefore $x^{2} \equiv 6 y^{2} \bmod 13$. But

$$
\left(\frac{6}{13}\right)=-1
$$

Therefore, there are no solutions for $k \equiv 6 \bmod 13$.

## A sufficient condition for $k$

## Lemma

Let $q>3$ be a prime number. Suppose that $k \in \mathbb{Z}$ is such that
(1) $k$ is not a square modulo $q$,
(2) $q \| k^{2}+k-3$.

Then there are no $k$ consecutive triangular numbers that add up to a triangular number.

## Example:

If $k \equiv 45 \bmod 53$ and $k \not \equiv 2430 \bmod 53^{2}$. There are 52 residues modulo $53^{2}$ which satisfy these conditions.

## Main Theorem

## Theorem

Let $K(x)$ be the number of $k$ 's less than $x$ that have solutions. Then:

$$
\sqrt{x} \leq K(x) \ll \frac{x}{\sqrt{\log (x)}} .
$$

## Finding $q$ such that $q \| k^{2}+k-3$ and $(k / q)=-1$

If $q \neq 13, k^{2}+k-3 \equiv 0 \bmod q$ has two distinct solutions $k_{1}, k_{2}$ whenever $(13 / q)=1$. We then have three possibilities
(1) Both $k_{1}, k_{2}$ are squares modulo $q$.
(2) One of $k_{1}, k_{2}$ is a square and the other one isn't.
(3) Neither $k_{1}, k_{2}$ are squares modulo $q$.

## A pair of important sets of primes

Let $\mathcal{A}$ be the set of primes $q$ for which we have $k_{1}, k_{2}$ both nonsquares modulo $q$.

Let $\mathcal{B}$ be the set of primes $q$ for which exactly one of $k_{1}, k_{2}$ is a square modulo $q$.

If $q \in \mathcal{A}$, then the proportion of residues modulo $q^{2}$ one must avoid are

$$
2 \frac{q-1}{q^{2}}=\frac{2}{q}-\frac{2}{q^{2}}
$$

If $q \in \mathcal{B}$, then the proportion of residues modulo $q^{2}$ one must avoid are

$$
\frac{q-1}{q^{2}}=\frac{1}{q}-\frac{1}{q^{2}}
$$

## Quantifying the proportion of primes in $\mathcal{A}, \mathcal{B}$

Consider $f(x)=x^{4}+x^{2}-3$. Let's analyze how $f(x)$ might factor in $\mathbb{Z}_{q}$. There are several possibilities

- $(1,1,1,1)$
- $(1,1,2)$
- $(2,2)$
- 4

Primes in $\mathcal{B}$ would split as $(1,1,2)$.
Primes in $\mathcal{A}$ would be primes that are squares modulo 13 and that don't split as $(1,1,2)$ or $(1,1,1,1)$.

## Chebotarev Density Theorem

## Theorem

Suppose that $f(x) \in \mathbb{Z}[x]$ is monic and irreducible over $\mathbb{Q}$, with $\operatorname{deg} f(x)=n$. Let $\mathbb{L}$ be the splitting field of $f(x)$ over $\mathbb{Q}$. Fix a partition $\left\langle k_{1}, \ldots, k_{r}\right\rangle$ of $n$ (that is, a tuple of positive integers $k_{1} \geq k_{2} \geq \cdots \geq k_{r}$ with $\left.k_{1}+\cdots+k_{r}=n\right)$. Let $\delta$ be the proportion of elements of $\operatorname{Gal}(\mathbb{L} / \mathbb{Q})$ which, when viewed as permutations on the roots of $f(x)$, have cycle type $\left\langle k_{1}, \ldots, k_{r}\right\rangle$. For all but finitely many primes $p$, the polynomial $f(x)$ factors as a product of distinct monic irreducible polynomials modulo $p$, and $\delta$ is the proportion of primes for which these irreducibles have degrees $k_{1}, \ldots, k_{r}$.

## Chebotarev in our problem

Consider $f(x)=x^{4}+x^{2}-3 . f$ is irreducible over $\mathbb{Q}$, let $\mathbb{L}$ be the splitting field of $f$ over $\mathbb{Q}$, then $\operatorname{Gal}(\mathbb{L} / \mathbb{Q})$ is isomorphic to

$$
\{(1),(1324),(12)(34),(1423),(34),(13)(24),(12),(14)(23)\}
$$

- 1 of the 8 elements decompose as ( $1,1,1,1$ )
- 3 of the 8 elements decompose as $(2,2)$
- 2 of the 8 elements decompose as $(1,1,2)$
- 2 of the 8 elements decompose as (4)

The proportion of primes $q \in \mathcal{B}$ is $2 / 8=1 / 4$.
The proportion of primes $q \in \mathcal{A}$ is $1 / 2-1 / 8-2 / 8=1 / 8$.

## Idea of Proof

There are several residues modulo certain squares of primes that must be avoided for $k$ to be able to yield solutions.
We then get the following upper bound heuristic:

$$
\begin{aligned}
K(x) & \ll x \prod_{\substack{q \leq x \\
q \in \mathcal{A}}}\left(1-\frac{2}{q}+\frac{2}{q^{2}}\right) \prod_{\substack{q \leq x \\
q \in \mathcal{B}}}\left(1-\frac{1}{q}+\frac{1}{q^{2}}\right) \\
& \ll x\left(\frac{1}{\left(\log ^{1 / 8} x\right)^{2}}\right)\left(\frac{1}{\log ^{1 / 4}(x)}\right) \\
& \ll \frac{x}{\sqrt{\log x}} .
\end{aligned}
$$

## Non-Chebotarev (weaker) proof

One could avoid the use of Chebotarev to get that $K(x)=o(x)$. Namely, the primes in $\mathcal{B}$ can be characterized as primes $q$ satisfying

$$
\left(\frac{13}{q}\right)=1 \quad \& \quad\left(\frac{-3}{p}\right)=-1
$$

The primes in $\mathcal{B}$ have proportion $1 / 4$.
Then

$$
K(x) \ll \frac{x}{(\log (x))^{1 / 4}} .
$$

## Main Theorem

## Theorem

Let $K(x)$ be the number of $k$ 's less than $x$ that have solutions. Then:

$$
\sqrt{x} \leq K(x) \ll \frac{x}{\sqrt{\log (x)}} .
$$

## On the hunt for a lower bound

Our goal is solving

$$
(2 m+1)^{2}-k(2 n+k)^{2}=\frac{(k-1)\left(k^{2}+k-3\right)}{3} .
$$

Let $p$ be a prime number satisfying:
(0) $p \equiv 7 \bmod 24$
(2) $p^{2}+p-3$ is not divisible by any prime $q$ for which $p \bmod q$ is a nonsquare
(3) $\mathbb{Q}(\sqrt{p})$ has class number 1 .

Then there exist $p$ consecutive triangular numbers that add up to a triangular number.

## $k=127$

We want to solve

$$
(2 m+1)^{2}-127(2 n+127)^{2}=682626=2 \times 3 \times 7 \times 16253
$$

- $127 \equiv 1 \bmod 42$
- $541^{2} \equiv 127 \bmod 16253$
- $\mathbb{Q}(\sqrt{127})$ has class number 1 .

Let $q \in\{2,3,7,16253\}$. There exists $x_{q}+y_{q} \sqrt{127}$ with norm $q$.

- $x_{2}=2175, y_{2}=193$
- $x_{3}=293, y_{3}=26$
- $x_{7}=45, y_{7}=4$
- $x_{16253}=2325, y_{16253}=206$

## Solution to $k=7$

$$
\begin{aligned}
& (45+4 \sqrt{127})(293+26 \sqrt{127})(2175+193 \sqrt{127})(2325+206 \sqrt{127}) \\
& =533462754763+47337164797 \sqrt{127}
\end{aligned}
$$

Let

$$
x=533462754763, \quad y=47337164797
$$

Then

$$
x^{2}-127 y^{2}=682626
$$

We want to solve $2 m+1=x$ and $2 n+127=y$.

$$
\begin{gathered}
m=266731377381, \quad n=23668582335 \\
\Delta_{n}+\Delta_{n+1}+\cdots+\Delta_{n+126}=\Delta_{m}
\end{gathered}
$$

## Cohen-Lenstra Heuristics

## Conjecture

Let $\mathcal{P}$ be the set of prime numbers $p$ satisfying
(1) $p \equiv 7 \bmod 24$
(2) $p^{2}+p-3$ is not divisible by any prime $q$ for which $p \bmod q$ is a nonsquare
(3) $\mathbb{Q}(\sqrt{p})$ has class number 1 .

The proportion of such primes is $75.45 \%$.
This suggests

$$
K(x) \gg \frac{x}{\log ^{3 / 2}(x)}
$$

## Thank you!
